

Describe your previous research experience or equivalent experience on complex projects, including the level of independence, while working as a member of a research/project team.

I am currently involved in three long-term research projects: two in computational biophysics, and one in quantum algorithms. Across these projects, I have worked independently to set up and run simulations, develop algorithms, analyze results, and produce visualizations, while periodically incorporating feedback from my mentors to refine my approaches.

As an undergraduate research assistant in the Vermaas lab at the MSU-DOE Plant Research Laboratory, I am working on understanding the effects of alcohols on bacterial membrane structure, with the broader goal of informing bioengineering efforts towards the design of tolerant strains for industrial biofuel production. Over the last four months, I have conducted end-to-end molecular dynamics (MD) simulations of bacterial membranes with varying alcohol concentrations. I prepare simulation systems using Visual Molecular Dynamics (VMD), run MD simulations on high-performance computing clusters like MSU's HPCC and NCSA DeltaAI using Nanoscale Atomistic Molecular Dynamics (NAMD), and analyze the resulting trajectories by computing membrane properties such as area per lipid, membrane thickness, and lipid order parameters using Python and Tcl. I am currently writing a first-author manuscript for this work, using the results from simulation to draw conclusions about membrane responses to solvent stress.

I have also spent the last year working on characterizing water transport modulation mechanisms in a capped aquaporin channel. The aim of this project is to understand plant drought tolerance and responses, and identify potential targets for increasing resilience to such abiotic stresses. I set up and run multiple MD simulations exposing the channel to different osmotic gradients, and analyze the resulting trajectories by computing pore radius profiles, water permeation rates, and ion distributions. I am also responsible for producing figures for meetings with experimental collaborators, and conferences such as ACS Fall 2025 and the First Great Lakes Plant Science Conference.

As an Honors Research Scholar, I am conducting research on quantum subgroup simulators under the guidance of Professor Ryan LaRose. My work involves developing methods for efficiently simulating quantum circuits on classical hardware, which is essential for the development and evaluation of larger-scale quantum algorithms that cannot yet be run on existing quantum hardware. Over the last three months, I have explored literature on group-theoretic and Lie-theoretic approaches to unitary subgroup membership, designed and implemented optimization routines to identify optimized gatesets for simulation, and created circuit rewriting algorithms to reduce computational costs. I discuss my progress weekly with Professor LaRose to reevaluate future directions and ensure alignment with larger research goals.
